Principal Components Analysis For Dummies

Principal component analysis (PCA) is a valuable technique that is widely used in predictive analytics and data science. It studies a dataset to learn the most relevant variables responsible for the highest variation in that dataset. PCA is mostly used as a data reduction technique. While building predictive models, you may need to reduce the number of features describing your dataset.

Principal Component Analysis in 6 steps - CoolStatsBlog

Principal Component Analysis is a well-known dimension reduction technique. It transforms the variables into a new set of variables called as principal components. These principal components are linear combination of original variables and are orthogonal. The first principal component accounts for most of the possible variation of original data. The second principal component does its best to capture the variance in the data.

Principal Component Analysis explained visually

Principal Component Analysis does just what it advertises; it finds the principal components of the dataset. PCA transforms the data into a new, lower-dimensional subspace—into a new coordinate system—. In the new coordinate system, the first axis corresponds to the first principal component, which is the component that explains the greatest amount of the variance in the data.
